Abstract

When building a metamodel for a complex computer simulation, the experiment design should exhibit good properties of both projectivity and orthogonality. We present a batch sequential experiment design method that produces uniformity in higher dimensions especially at certain stages of the design, but approximates those properties after every stage.

Problems with a Design with Fixed Design Points

□ More data may be needed if desire precision is not met

A waste of effort if fewer experiments suffice

□ Information collected cannot be used to improve design

Advantages of Sequential Designs

• Can still be implemented if budget is unknown. Can terminate at any time

Overview of SFFLHD

sFFLHD uses the idea of sliced space filling designs by (Qian, 2009) and extends Loeppky, Moore and Williams's batch sequential design (Loeppky et al, 2010)

□ Space filling properties at certain stages of the design (golden stages).

Good orthogonality and projectivity at intermediate stages.

□ More batches can easily be sampled if needed.

Variance Reduction of Mean Estimators

Each batch achieves the same variance reduction as an ordinary LHD comparing to random sampling

$$Var(\overline{Y_p^r}) = \sum_{|u| \ge 2} M_p^r(u, |u|) L^{-2} Var(\alpha_u(\mathbf{x})) + o(L^{-1})$$

More variance reduction is achieved when the sequential design is an OA-based LHD

$$Var(\overline{Y}) = \sum_{|u| \ge 3} M(u, |u|) l^{-2} Var(\alpha_u(\mathbf{x})) + o(l^{-1})$$

Certain degree of variance reduction at other stages

Batch	1	4	8	12	16
Design Points	8	32	64	96	128
sFFLHD	9.386	1.253	0.051	0.178	0.020
bMmLHD	245.810	46.817	18.310	5.051	0.436
MmDist	13.834	32.051	14.866	6.425	4.510
rsFFLHD	155.487	43.463	0.047	1.347	0.019

Comparison of RMSE of $\hat{\mu}$ for each design scheme Table for Borehole function

Department of Industrial Engineering and Management Sciences, Northwestern University

The big grid design W, nonoverlapping OAs, preserves orthogonality.

The small grid design V, a (near) LH, preserves LHD projectivity.

Levels of V are determined according to W and expand if necessary to accommodate more design points.

Sampling X is drawn according to the near LH V similar to LHD method

The sequential design can continue indefinitely.

model fit.

MSE in Gaussian Model Fitting

Conclusions

•In low dimensional examples, sFFLHD performs as well or nearly as well in terms of RMSE of the GP

•In high dimensional examples, sFFLHD produces lower RMSE of the GP model fit

•sFFLHD dominates the other tested designs in estimating the mean.

•Each batching being an LHD contributes substantially to sFFLHD's good performance if the design does not reach the orthogonal stages.
