# General constrained optimization

$$\min_{\mathbf{x}} f(\mathbf{x}), \quad \text{s.t.}, \quad c(\mathbf{x}) \leq 0,$$

where  $f$  and  $c$  may be **blackboxes**.

Except in a few special cases, we don't have statistical tools to solve this problem.

- ▶  $c(\mathbf{x})$  is linear, you can use EI (Jones, et al. 1998)
- ▶  $c(\mathbf{x}) \in \{0, 1\}$ , you can try IECl (G. & Lee, 2011)

That's a shame because stats methods have lots to offer:

- ▶ global solutions/robustness/UQ
- ▶ a monopoly on methods for noisy simulator evaluations

In fact, in many **real** constrained optimization problems are **easier**, but we still don't have solutions:

- ▶ the objective  $f$  may be known and **linear**
- ▶ the hard part is the constraint function

Examples include any problem where resource costs can be summed, but one cannot know whether the allocation is sufficient without expensive simulation/experimentation.

- ▶ **Goal:** tackle problems like these while retaining benefits of statistical optimization.

## Motivation: pump-and-treat

A “hypothetical” groundwater contamination scenario based on the Lockwood Solvent Groundwater Plume Site located near Billings, Montana ([Tetra Tech Inc., 2003](#))

- ▶ Industrial practices have resulted in the development of two separate plumes containing chlorinated solvents that threaten the Yellowstone river.
- ▶ Six pump-and-treat wells have been proposed to prevent further expansion.
- ▶ The optimization objective is to contain both plumes using the minimum amount of pumping.

# Pressure gradients

An **analytic element method (AEM)** groundwater model is used to simulate the amount of contaminant exiting both boundaries under pumping scenarios (Craig & Matott, 2005).

So the constrained optimization problem is:

$$\min_{0 \leq x_j \leq 2 \times 10^5} \sum_{j=1}^6 x_j, \quad \text{s.t. } c_{1,2}(\mathbf{x}) \leq 0,$$

- ▶ a linear objective (pumping rates), and
- ▶ two expensive (to evaluate) quantified constraints on the amount of contaminant existing the system.
  - ▶ a large highly non-convex satisfaction region; very narrow in the neighborhood of the optimum

MATLAB and Python optimizers use an **additive penalty method** (APM; Matott, et al, 2011; Hilton and Culver, 2000)

New best is [MADS](#), from [S. Le Digabel, et al.](#)

## A baseline

Here is a strategy that leverages the simplicity of the underlying objective:

For  $n = n_{\text{start}}, \dots$  (i.e., at each trial), do

- ▶ Let  $y_n^* = \min_{i=1, \dots, n} \{ \sum_j x_{ij} : c_{1,2}(\mathbf{x}_i) = 0 \}$
- ▶ Choose  $\mathbf{x}_{n+1} \sim \text{Unif}([0, 2 \times 10^5]^6)$  s.t.  $\sum_j x_{n+1,j} < y_n^*$

A good starting point is  $\mathbf{x} = (1 \times 10^5)^6$ , which is valid.

- ▶ No modeling or other calculation required,
- ▶ except maybe a rejection sampling routine.

Sampling only from the objective improvement region.

## Finding the constraint boundary

Due to the linearity of the objective, the solution must lie on the constraint boundary.

At each trial, fit a **classification model** to data pairs comprised of  $(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_n, y_n)$  where

$$y_i = \mathbb{I}(c_1(\mathbf{x}_i) = 0) \times \mathbb{I}(c_2(\mathbf{x}_i) = 0).$$

- ▶ we use a classification GP (CGP) via **plgp** package for R

Among candidates improving on the objective, choose  $\mathbf{x}_{n+1}$  via an **active learning** heuristic

- ▶ we use predictive class-entropy

## CGP/entropy active learning.

## Pros:

- ▶ Global.
- ▶ Uses important analytic information (about the objective)
- ▶ Make a use of rich constraint information (by forecasting)

## Cons:

- ▶ Does not use constraint quantification information.
- ▶ Entropy is a poor active learning heuristic—too **myopic**, although choosing from the improvement region helps.

# Augmented Lagrangian

The *augmented Lagrangian* is a penalty function often used in optimization contexts due to favorable asymptotic properties.

It offers an amenable framework for balancing a scalar objective  $f$  and vector-valued constraints  $c$ :

$$L_A^{\lambda, \mu}(\mathbf{x}) = f(\mathbf{x}) + \lambda^\top c(\mathbf{x}) + \mu^\top c(\mathbf{x})^2$$

see, e.g., [Kannan & Wild \(2012\)](#).

Optimizing  $L_A^{\lambda, \mu}(\mathbf{x})$  by unconstrained methods leads to good *intermediate* solutions.

When the tuning parameters  $\lambda, \mu$  follow particular updating rules, e.g.,

$$\lambda' = \lambda + \mu^\top c(x^*), \quad \mu' = \rho\mu, \quad \text{for } \rho > 1$$

implementing heavier penalization of constraint violations in the composite objective as the algorithm progresses

- ▶ convergence is guaranteed to a local, *valid*, solution under very mild conditions.
- ▶ A little like **simulated annealing** but **not** guaranteeing a **global** solution.

Expected Improvement (EI) offers global scope and the ability to accommodate noise.

In each trial:

- ▶ Let  $y(\mathbf{x}) = L_A^{\lambda, \mu}(\mathbf{x})$ , and fit a surrogate model to  $(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_n, y_n)$ .
- ▶ Let  $y^* = \min\{y_1, \dots, y_n\}$  and define

$$I(\mathbf{x}) = \max\{y^* - Y(\mathbf{x}), 0\}, \quad \text{for surrogate } Y(\mathbf{x}).$$

- ▶ Choose  $\mathbf{x}_{n+1}$  to maximize  $\mathbb{E}\{I(\mathbf{x})\}$  using candidates  $\mathbf{x}$ , possibly only those improving on the objective;
- ▶ update  $\lambda$  and  $\mu$  at convergence and restart with new  $y$ .

El on augmented Lagrangian objective with GP surrogate.

## Pros:

- ▶ Uses quantified constraint information.
- ▶ Easily extended to non-trivial objective functions.\*

## Cons:

- ▶ Does not leverage that the solution is on the constraint boundary.
- ▶ EI behaves strangely: **global scope is hurting**.
- ▶ Composite objective is **pathologically non-stationary**, which makes choosing surrogate modeling hard.
- ▶ Unnecessarily models a known objective.\*

One thought is to use a non-stationary surrogate model, like `tgpr`.

- ▶ that helps a little, but it only addresses one of the **cons.**

A better idea may be to **separately model each of the components** of  $L_A^{\lambda, \mu}(\mathbf{x})$ :  $f, c_1, \dots, c_m$ .

- ▶ In many cases, surrogate  $Y_f(\mathbf{x})$  may not be needed for  $f$ .
- ▶ GPs can be used for each  $c_i$ , producing surrogates  $Y_{c_i}(\mathbf{x})$ .
- ▶ Then  $Y(\mathbf{x}) = Y_f(\mathbf{x}) + \lambda^\top Y_c(\mathbf{x}) + \mu^\top Y_c(\mathbf{x})^2$  is a surrogate for  $L_A^{\lambda, \mu}(\mathbf{x})$ .

Unfortunately, the composite  $Y(\mathbf{x})$  does not easily emit an analytic EI statistic.

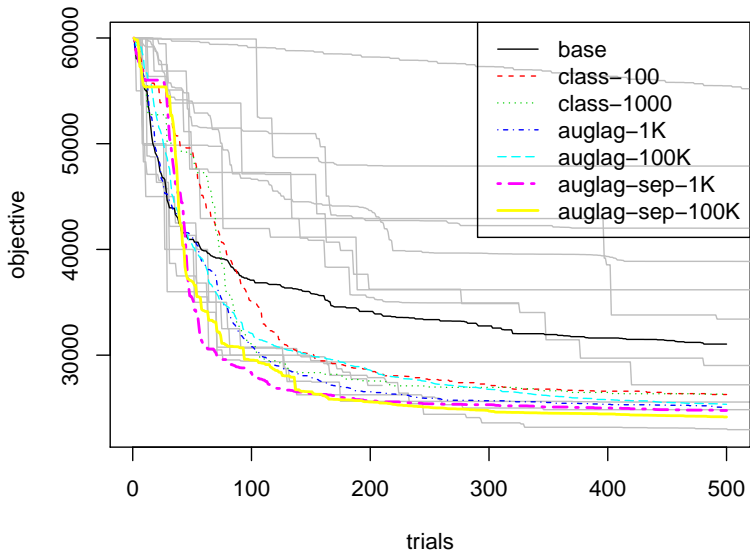

- ▶ We're working on it.
- ▶ Numerical evaluation is harder than you might think.

But it can still be useful, since  $\mathbb{E}\{Y(\mathbf{x})\}$  is analytic.

For each trial

- ▶ choose  $\mathbf{x}_{n+1}$  to maximize  $\mathbb{E}\{Y(\mathbf{x})\}$  using candidates  $\mathbf{x}$ , possibly only those improving on the objective,  $f$
- ▶ update  $\lambda$  and  $\mu$  at convergence and restart with new  $Y_f$ , and  $Y_{c_i}$

## Separated augmented Lagrangian surrogate model(s).

## Pros:

- ▶ Uses quantified constraint information.
- ▶ Easily extended to non-trivial objective functions.

## Cons:

- ▶ Without EI, no longer global in scope.
- ▶ Does not leverage that the solution is on the constraint boundary.
- ▶ GP surrogate models  $Y_{c_i}(\mathbf{x})$  may find the limiting “kink” at zero difficult to emulate.

# Wrapping up

El and related methods offer very compelling solutions to hard (global) optimization problems.

**But** not ones that are often encountered in practice.

- ▶ We are lacking good ideas for dealing with constraints.

**This talk** has shown that the integration of several small ideas can add up in a big way.

More synergies are need:

- ▶ new surrogate modeling ideas
- ▶ new improvement heuristics combining quantifiable constraints and analytic structure
